

Evaluation of preoperative parathyroid imaging modalities within a provincial hospital setting

Bonnet LA (BMedSt, MD), **Bonnet GC** (MB ChB, M.MED (surg), FCS), **Skavysh A** (MD, Am Bd Cert Surg), **Osman M** (FFR RCSI, RANZCR)
Whanganui District Hospital, Whanganui, New Zealand.

Background

Primary hyperparathyroidism affects approximately 30 in 100,000 people in NZ annually; predominantly in their 3rd to 6th decade of life.(1) Accurate pre-operative localisation and characterisation of parathyroid adenoma assists in surgical planning. As new imaging techniques become available; evaluating their sensitivity and localisation accuracy ensures a continued high standard of patient care.

Aims

- To evaluate the sensitivity and localisation accuracy of preoperative parathyroid imaging modalities currently implemented within Whanganui District Hospital.
- Ultrasound (US), Nuclear medicine (NM) and 4D-CT.**
- Guide clinical decision making pre-operatively
- Avenue for potential standardisation of imaging protocols preoperatively within a provincial hospital settings.

Methodology

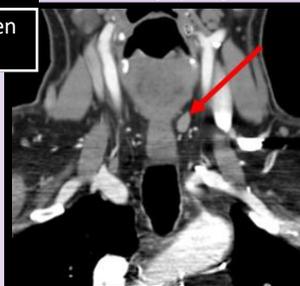

- Quantitative, single-institution, retrospective study
- Data collection from 2018, continuing prospectively
- Patient selection within WDHB catchment who met inclusion criteria
- Imaging localisation accuracy & sensitivity determined relative to intraoperative findings and histology reports

Inclusion Criteria

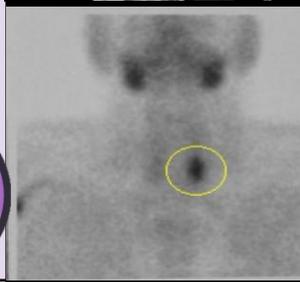

- Hypercalcemia ($Ca^{2+} >2.55$), Hyperparathyroidism (PTH >7.0)
- Parathyroidectomy within WDHB since 2018
(excluded if opted for no surgical intervention)

Results

Parathyroid adenoma seen on ultrasound.(3)

Left parathyroid adenoma using 4D computed Tomography (3)

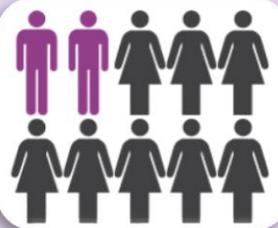

Left parathyroid adenoma using Tc-99m nuclear medicine imaging.(3)

Conclusion

- 4D-CT had the greatest localisation accuracy (100%) which is due to its high image resolution, multi-planar ability; allowing for superior anatomical localisation for both eutopic and ectopic parathyroid localisations. Nuclear medicine (Tc-99m) was the most sensitive imaging modality (90.0%) which is reflective of its functional uptake capability for tissue-type delineation.
- US was the least sensitive (35.3%) and least accurate (60.0%) imaging modality significantly affected by anatomical variability.
- Combined US protocols with NM (93.5%) and 4DCT (90.0%) were as sensitive as single-study imaging techniques alone.

Discussion

- Sensitivity and localisation accuracy of NM and 4D-CT within this study are reflective of current literature (at 95% confidence range).(1,2)
- Small sample size limits statistical power and sub-data set analysis. Prospective nature allows ongoing analysis and revisitation in 12-24months.
- Areas for further research include; side-effect profile, imaging-duration and preparation, cost-effectiveness.
